## **03 - Reproducibility and Version Control** ml4econ, HUJI 2021

Itamar Caspi March 21, 2021 (updated: 2021-04-01)

## **Replicating this Presentation**

R packages used to produce this presentation

library(tidyverse) # for data wrangling and plotting library(tidymodels) # for modeling the tidy way library(knitr) # for presenting tables library(xaringan) # for rendering xaringan presentations

If you are missing a package, run the following command

```
install.packages("package_name")
```

Alternatively, you can just use the **pacman** package that loads and installs packages:

if (!require("pacman")) install.packages("pacman")

pacman::p\_load(tidyvers, tidymodels, knitr, xaringan)

## From Best Practices to Methodology

Best Practice	Methodology		
High dimensional statistics	Machine learning		
<pre># code annotation</pre>	Notebooks (R Markdown, Jupyter)		
<pre>mydoc_1_3_new_final_23.docx</pre>	Version control		
Ready to use tables (xlsx)	Generate tables (SQL, dplyr, pandas)		
??	Reproducibility		
Stata, SAS, EViews	R, Python, Julia		
work solo	Interdisciplinary teams		

## Outline

- 1. Reproducibility
- 2. The Tidyverse
- 3. Version Control
- 4. GitHub

# **RStudio Projects**

## Reproducibility

- Reproducible research allows anyone to generate your exact same results.
- To make your project reproducible you'll need to:
  - document what you did (code + explanations).
  - name the packages you used (including version numbers).
  - describe your R environment (R version number, operating system, etc.)
- Being in a "reproducible" state-of-mind means putting yourself in the shoes of the consumers, rather than producers, of your code.

(In "consumers" I also include the future you!)

## An Aside: renv

The renv package, by RSudio, helps you create reproducible environments for your R projects.

renv will make your R projects more (From the renv documentation):

- **Isolated**: Installing a new or updated package for one project won't break your other projects, and vice versa. That's because renv gives each project its own private package library.
- **Portable**: Easily transport your projects from one computer to another, even across different platforms. renv makes it easy to install the packages your project depends on.
- **Reproducible**: renv records the exact package versions you depend on, and ensures those exact versions are the ones that get installed wherever you go.

For further details, see this introduction.

## An Aside: Docker

- **Docker** is a virtual computer inside your computer.
- Docker makes sure that anyone running your code will be able to perfectly reproduce your results.
- Docker solves a major predictability barrier: replicating your entire development environment (operating system, R versions, dependencies, etc.).
- For further details, see **rOpenSci's tutorial**.

## RStudio Project Environment

- If your R script starts with setwd() or rm(list=ls()) then are doing something wrong!
- Instead:
  - 1. Use RStudio's project environment.
  - 2. Go to Tools -> Global Options -> General and set the "Save workspace to .RData on exit" to NEVER.

## R Markdown

- R Markdown notebooks, by RStudio, are perhaps THE go-to tool for conducting reproducible research in R.
- The process of "knitting" an Rmd file starts with a clean slate.
- An R Markdown file integrates text, code, links, figures, tables, and all that is related to your research project.
- R Markdown is perfect for communicating research. One if its main advantages is that an \*.Rmd file is a "meta-document" that can be exported as a:
  - document (word, PDF, html, markdown).
  - presentation (html, beamer, xaringan, power point)
  - website (blogdown).
  - book (bookdown).
  - journal article (pagedown)
  - dashboard (flexdashboards).

The Tidyverse

## This is Not a Pipe

## Prerequisite: %>% is a pipe

- The "pipe" operator %>% introduced in the magrittr package, is deeply rooted in the tidyverse.
- To understand what %>% does, try associating it with the word "then".
- Instead of y <- f(x), we type y <- x %>% f(). This might seen cumbersome at first, but consider the following two lines of code:

> y <- h(g(f(x), z))

> y <- x %>% f() %>% g(z) %>% h()

The second line of code should be read as: "take x, *then* put it through f(), *then* put the result through g(. , z), *then* put the result through h(), and finally, keep the result in y.

## Morning Routine

```
leave_house(get_dressed(get_out_of_bed(wake_up(me, time =
"8:00"), side = "correct"), pants = TRUE, shirt = TRUE), car
= TRUE, bike = FALSE)
```

```
me %>%
wake_up(time = "8:00") %>%
get_out_of_bed(side = "correct") %>%
get_dressed(pants = TRUE, shirt = TRUE) %>%
leave_house(car = TRUE, bike = FALSE)
```

## Base R vs. the Tidyverse

• Consider the following data frame:

• Can you guess what the following code chunk does?

```
df_new <- df[df$x > 0, c("x", "y")]
df_new$xx <- df_new$x^2</pre>
```

• How about this one?

```
df_new <- df %>%
   select(x, y) %>%
   filter(x > 0) %>%
   mutate(xx = x^2)
```

## How to read "piped" code?

df\_new <- df %>%
 select(x, y) %>%
 filter(x > 0) %>%
 mutate(xx = x^2)

The above code chunk should be read as:

"generate a new dataframe df\_new by taking df, then select x and y, then filter rows where x is positive, then mutate a new variable  $xx = x^2$ "

## Pros & cons

- Following a "tidy" approach makes your code more readable  $\Rightarrow$  more reproducible.
- I believe that there is a growing consensus in the #rstats community that we should **learn the tidyverse first**.
- Nevertheless, note that the tidyverse is "Utopian" in the sense that it strives toward *perfection*, and thus keeps changing. By contrast, base R was built to last.
- As usual, being proficient in both (base R and the tidyverse) will get you far...

## Tidyverse Packages

Which packages come with tidyverse?

tidyverse\_packages()

## [1] "broom" "cli"
## [7] "ggplot2" "haven"
## [13] "magrittr" "modelr"
## [19] "reprex" "rlang"
## [25] "tidyr" "xml2"

"crayon" "dbplyr" "hms" "httr" "pillar" "purrr" "rstudioapi" "rvest" "tidyverse" "dplyr" "jsonlite" "readr" "stringr" "forcats" "lubridate" "readxl" "tibble"

Note that not all these packages are loaded by default (e.g., lubrudate.)

We now briefly introduce one the tidyverse flagships: dplyr.

## dplyr: The grammar of data manipulation

dplyr is THE go-to tool for data manipulation

- Key "verbs":
  - filter() selects observations (rows).
  - select() selects variables (columns).
  - mutate() generate new variables (columns).
  - arrange() sort observations (rows).
  - summarise() summary statistics (by groups).

#### • Other useful verbs:

group\_by() - groups observations by variables.
sample\_n() - sample rows from a table.

• And much more (see dplyr documentation)

## The tidymodels package

• Tidymodels extends the tidyverse "grammar" philosophy to modelling tasks.

tidymodels::tidymodels\_packages()

##	[1]	"broom"	"cli"	"crayon"	"dials"	"dplyr"
##	[6]	"ggplot2"	"infer"	"magrittr"	"parsnip"	"pillar"
##	[11]	"purrr"	"recipes"	"rlang"	"rsample"	"rstudioapi"
##	[16]	"tibble"	"tidytext"	"tidypredict"	"tidyposterior"	"tune"
##	[21]	"workflows"	"yardstick"	"tidymodels"		

For further details, visit the **tidymodels GitHub repo**.

- 4. Data Visualiztion: A practical introduction by Kieran Healy.

# Version Control

### **Version Control**

- Git is a distributed version control system.
- Huh?!
- Sorry. Think of MS Word "track changes" for code projects.
- Git has established itself as the defacto standard for version control and software collaboration.

### GitHub

- GitHub is a web-based hosting service for version control using Git.
- OK, OK! Think of "Dropbox" for git projects. On steroids. And then some.
- GitHub is where and how a large share of open-source projects (e.g., R packages) are being developed.

### Resources

- 1. Happy Git and GitHub for the useR by Jenny Bryan.
- 2. Version Control with Git(Hub) by Grant McDerrmot.
- 3. Pro Git.

# Let's Practice!

## Suggested workflow for starting a new (desktop) R project

RStudio:

- 1. Open RStudio.
- 2. File -> New Project -> New Directory -> New Project.
- 3. Name your project under "Directory name:". Make sure to check "Create git repository".

GitHub Desktop:

- 1. Open GitHub Desktop.
- 2. File -> Add local repository.
- 3. Set "Local path" to your RStudio project's folder.
- 4. Publish local git repo on GitHub (choose private or public repo).

## Suggested workflow for starting a new RStudio Cloud project

- 1. Login to RStudio Cloud.
- 2. Choose workspace (e.g., ml4econ-2020).
- 3. Click on "New Project" (optional from GitHub).
- 4. Set up Git: Tools -> Version Control -> Project Setup -> set "Version Control System" to "Git" and restart session.
- 5. Introduce yourself to Git

```
install.packages("usethis")
library(usethis)
use_git_config(
   scope = "project",
    user.name = "Jane",
   user.email = "jane@example.org"
)
```

(6. Some extra steps are needed in order to publish and sync this new project with GitHub.)

## Suggested Git Workflow (Optional)

The **pull -> stage -> commit -> push** workflow:

- 1. Open GitHub Desktop.
- 2. Change "Current repository" to the cloned repo.
- 3. Click "Fetch origin" and **pull** any changes made to the GitHub repo.
- 4. Open your project.
- 5. Make changes to one or more of your files.
- 6. Save.
- 7. **stage** or unstage changed files.
- 8. write a summary (and description) of your changes.
- 9. Click "Commit to master".
- 10. Update remote: Click "**Push** origin" (Ctrl + P).

## Clone and Sync a Remote GitHub Repository (Optional)

#### Cloning:

- 1. Open GitHub Desktop.
- 2. Open the remote repository.
- 3. Click on "Clone or download".
- 4. Set the local path of your cloned repo (e.g., "C:/Documents/CLONED\_REPO".

#### Syncing:

- 1. Open GitHub Desktop.
- 2. Change "Current repository" to the cloned repo.
- 3. Click the "Fetch origin" button.
- 4. **Pull** any changes made on the remote repo.

### Your Mission

- 1. Open RStudio (or login to RStudio Cloud.)
- 2. Create your first R project.
- 3. Initiate Git.<sup>1</sup>
- 4. Create a new RMarkdown file.
- 5. Commit.

<sup>1</sup> RStudio automatically generates a .gitignore file that tells git which files to ignore (duh!). Click here for further details on how to configure what to ignore.
