Embracing Big Data Workload in Cloud Native Environment with Data Locality

Sammi Chen & Xiaoyu Yao

About us

- Sammi Chen – Senior software engineer from Tencent Cloud, Apache Hadoop Committer and PMC, working on Apache Hadoop HDFS/Ozone.

- Xiaoyu Yao – Principal software engineer from Cloudera, Apache Hadoop Committer and PMC, working on Apache Hadoop HDFS/Ozone.

Outline

- Big data evolution in cloud native environment
- Data Locality and why it matters
- Data locality in big data storage
  - Apache Hadoop HDFS
  - Apache Hadoop Ozone
- Apache Ozone in in Kubernetes
- Q&A

Big Data Evolution in Cloud Environment

- Co-located Compute and Storage

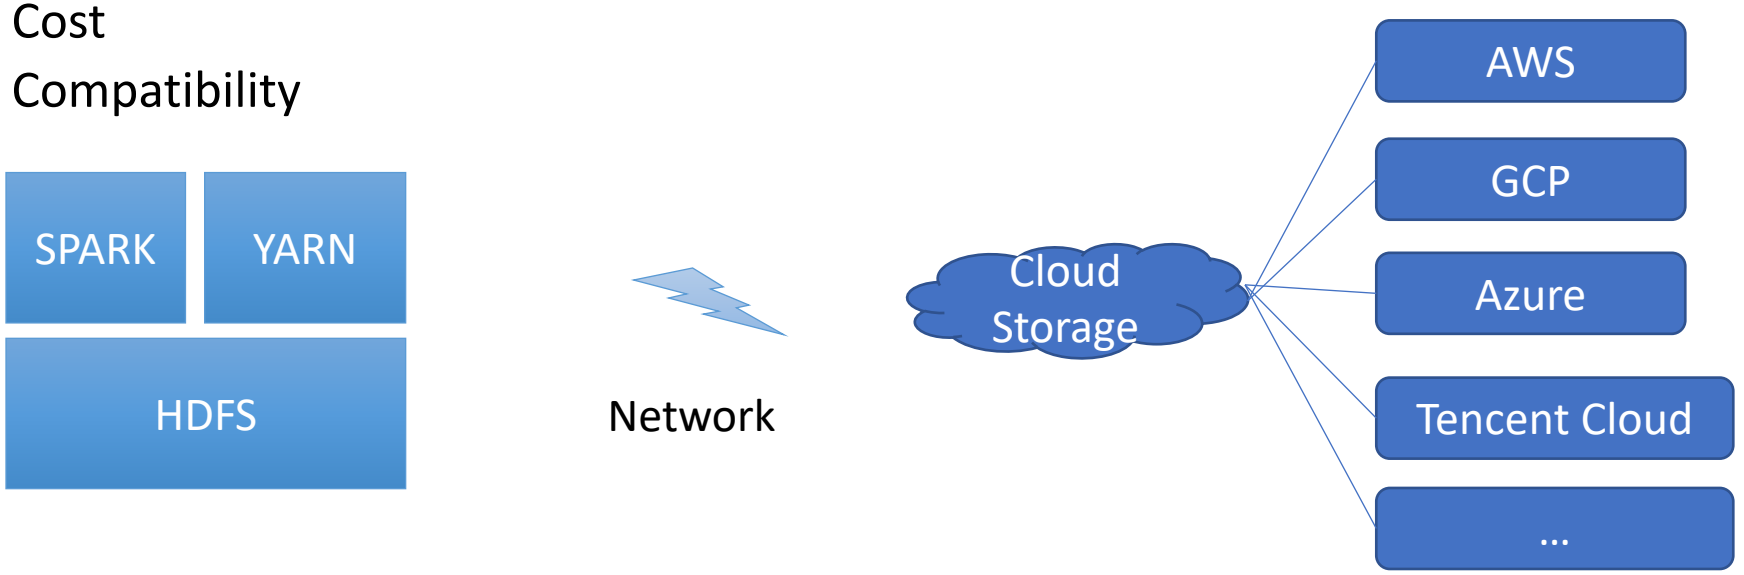
  - Pros
    - Fast storage access with locality
    - Less network traffic
    - Cost-effective for I/O intensive OLAP workloads (MapReduce/Hive/Impala)
  - Cons
    - Limited Elasticity: Requirements for Storage nodes and compute node are different.
    - Elastically scale storage node with compute node is difficult and may not cost-effective.

Big Data Evolution in Cloud Environment

- Separation of Compute and Storage
  - Pros
    - Elastically scale compute independent of storage
    - Cost-effective for compute-intensive workload(ML)
  - Cons
    - Lose storage locality
    - More network traffic for storage access
    - More CPU cycle (e.g., Erasure Coding)

Big Data Evolution in Cloud Environment

- Hybrid-Cloud and Multi-Cloud
  - Pros
    - Support locality for I/O intensive workload
    - Allow agile access, e.g., ML on multi-cloud
  - Cons
    - Cost
    - Compatibility



Challenges of Cloud Native Env for Big Data

Scheduler

- Optimize resource utilization(CPU/GPU/Memory/etc.)

Networking

- Optimize bandwidth usage.

Storage

- Optimize external storage access ?

Locality in Big Data

- What is Locality?

  Local Node: Data local to the compute node

  Local Rack: Data in the same rack with the compute node

  Local DC: Data in different rack/zone but closer to the compute node

Locality in Big Data - Benefit

- Higher throughput
- Less network traffic
- Fast job execution
- Better cluster utilization

Locality in Big Data - Scheduling

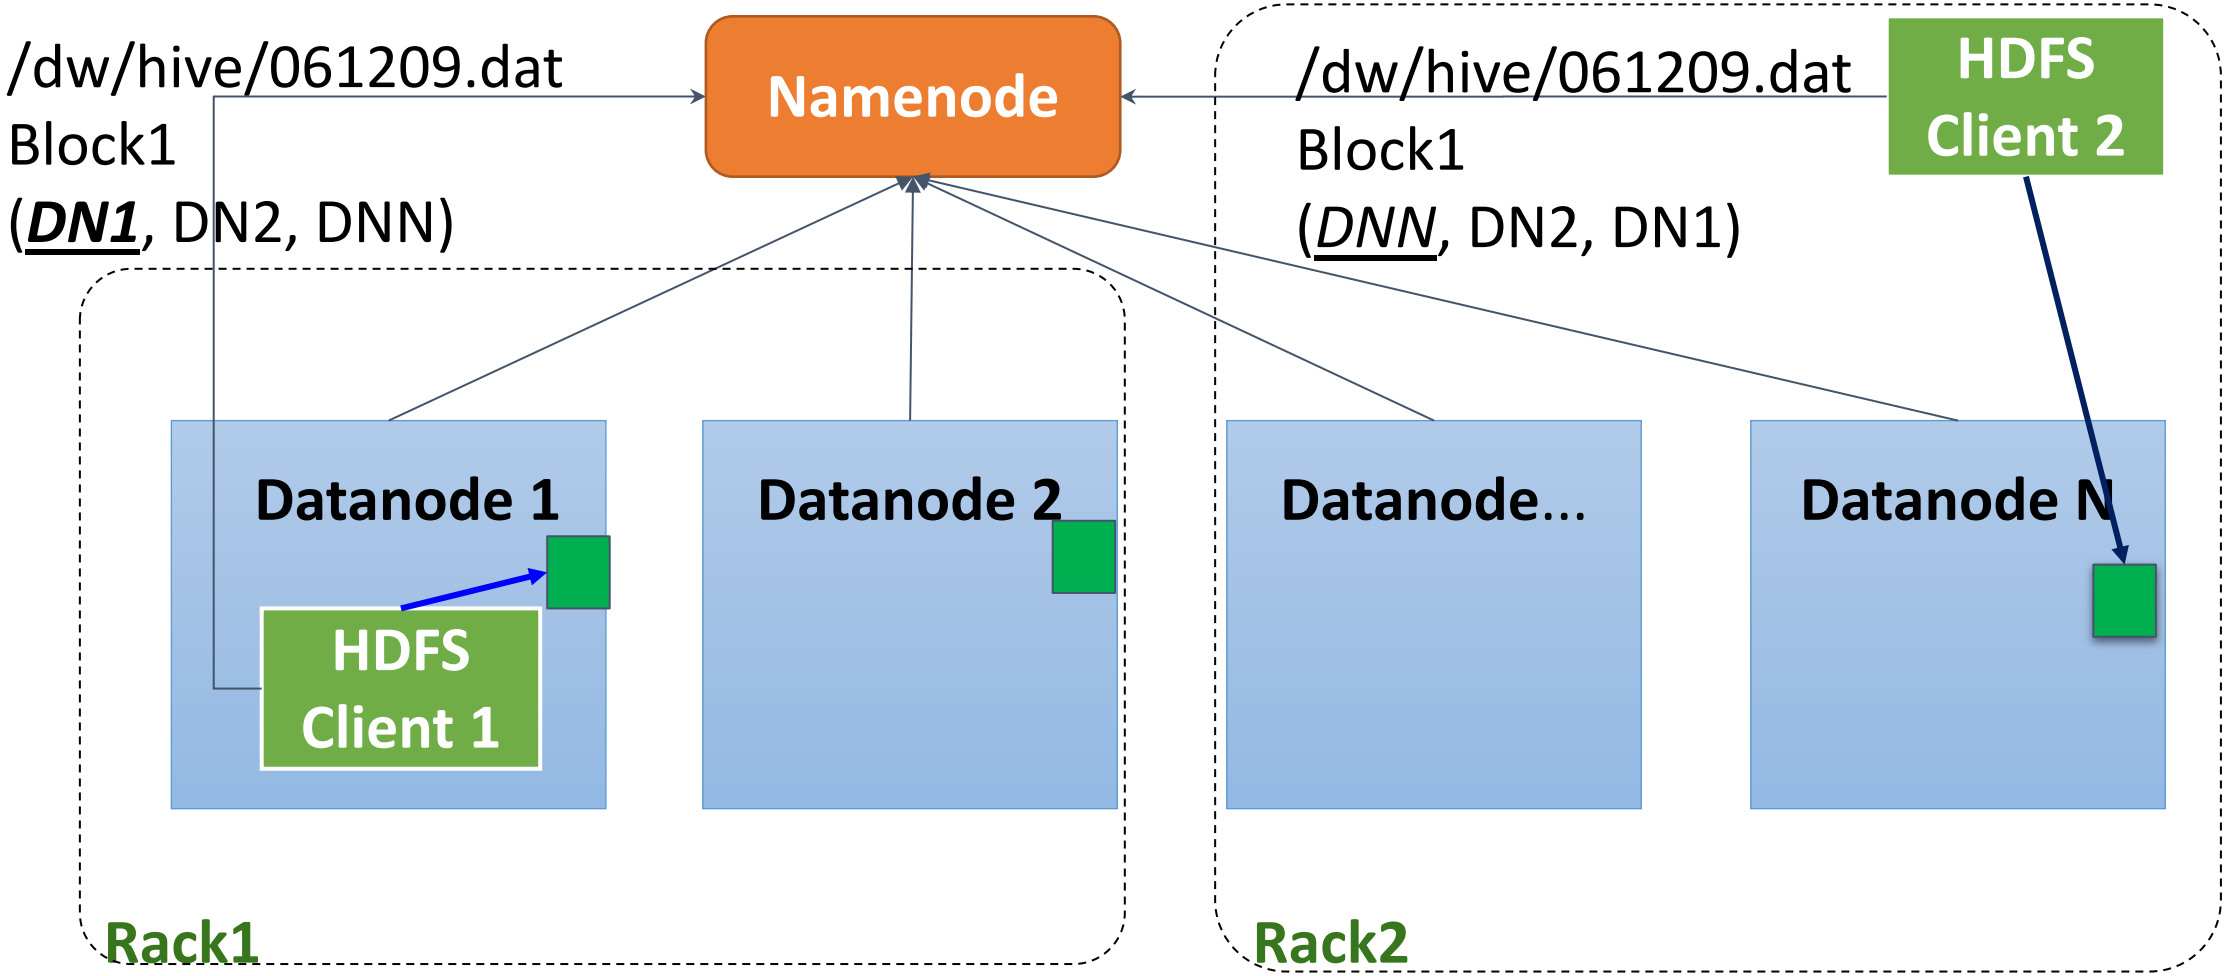
- Apache YARN
  - Support locality aware task scheduling via InputSplits
- Apache SPARK
  - Spark support locality aware scheduling of RDDs via spark.locality levels
    - PROCESS_LOCAL
    - NODE_LOCAL
    - RACK_LOCAL
    - ANY
  - Spark on K8s elastically schedule driver/executor pods with node selector

Locality in Big Data Storage (HDFS)

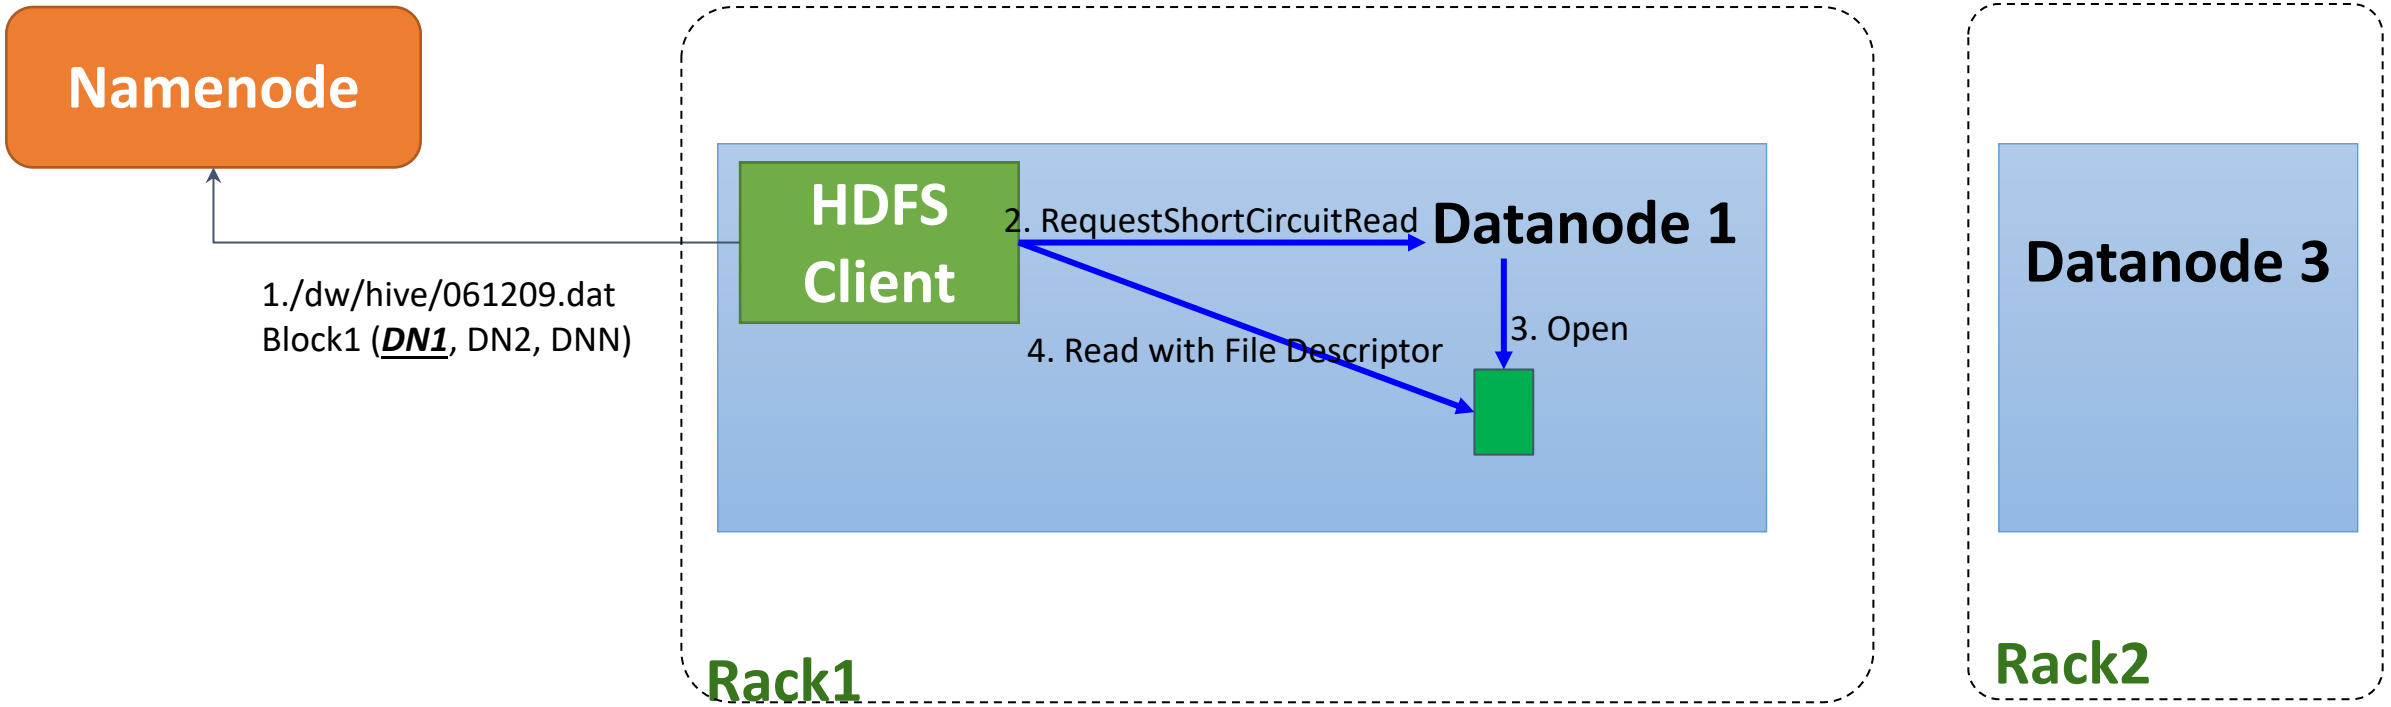
Apache Hadoop HDFS

- Scalable Distributed File System
  - Fast file system metadata access (200K ops/s)
  - Hundreds PBs in capacity
  - Thousands of nodes per cluster
  - Scale horizontally
  - Strong consistency
  - Resilient to failures
  - …

Hadoop HDFS Locality
Rack aware access



Hadoop HDFS Locality – Short Circuit Read



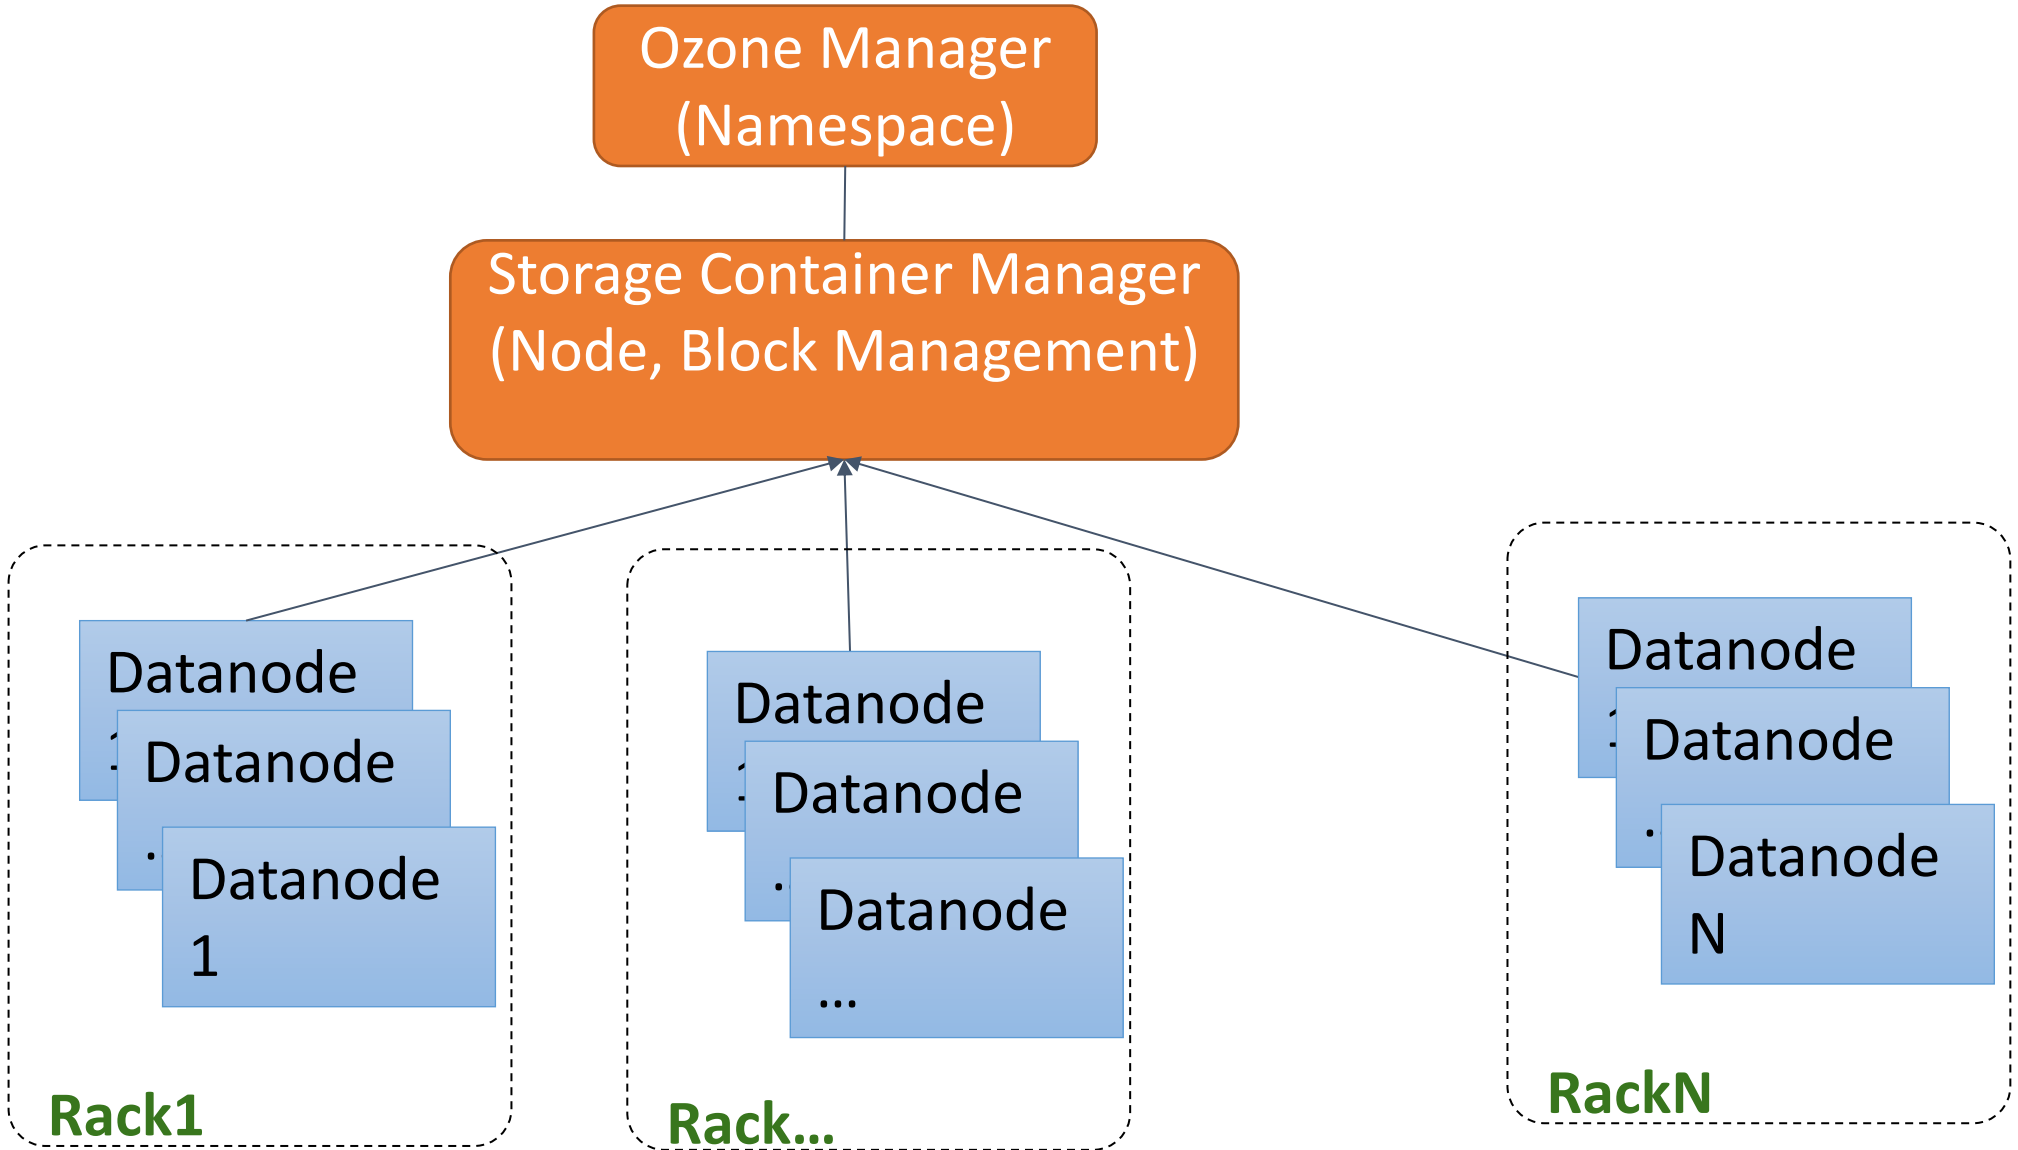
Apache HDFS in Kubernetes

- Challenges
  - Monolithic namenode
    - Small Files problem
      - 300 million+ files need special GC tuning
      - Take long time to upgrade/restart
  - Expose datanode locality
- Opportunities
  - Cloud native storage orchestra
    - Existing big data workload: Analytic/IoT/Streaming, etc.
    - Upgradable from existing HDFS clusters with hundreds or thousands of nodes.

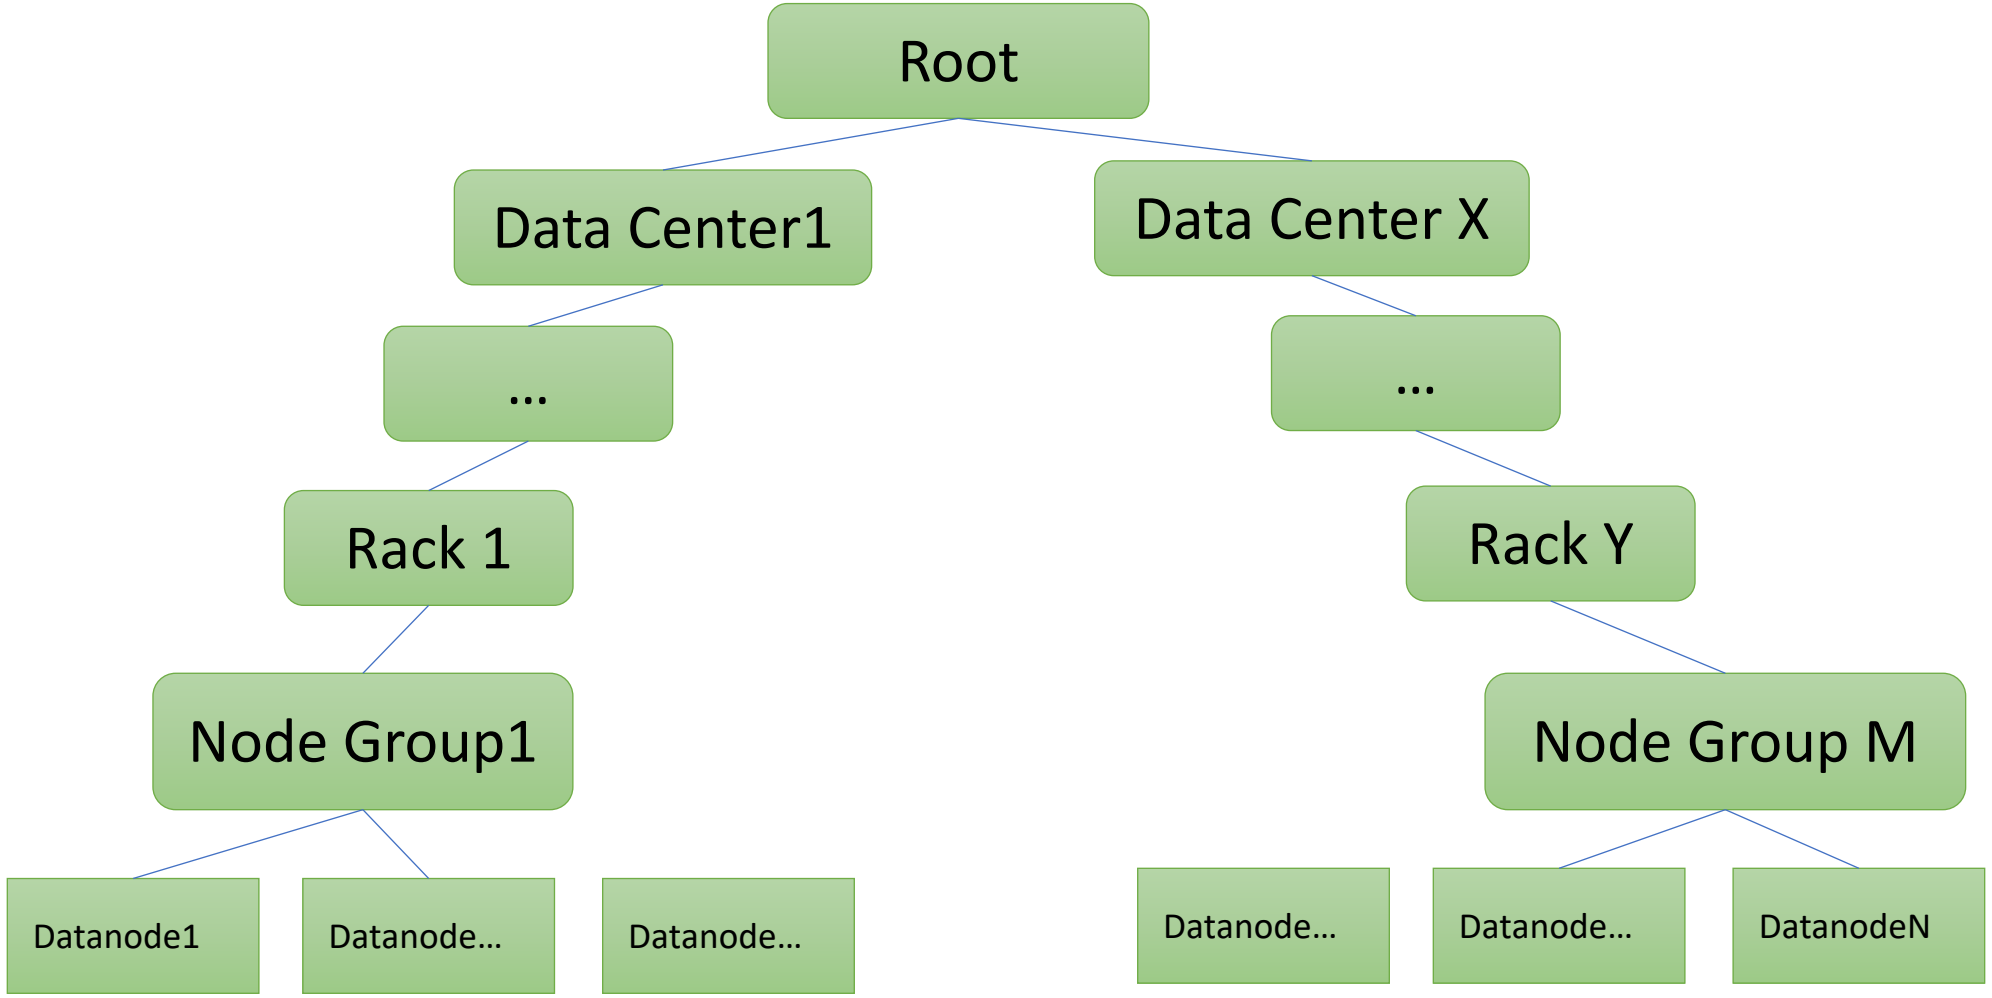
Locality in Big Data – Storage (Apache Ozone)

- Scalable, redundant, and distributed object store
- Scaling to billions of objects of varying sizes.
- Decoupled micro-services that support Kubernetes deployment.
- Support topology aware data placement and access.
- Support S3 access
- Support in-place upgrade from HDFS
- …

Apache Ozone Overview



Apache Ozone Topology



Apache Ozone Locality

- Highly customizable topology schema
  - /DataCenter/NodeGroup/Rack/Datanode.
- Topology aware access policy
  - Ozone manager returns topology ordered datanodes list for client access
  - Client access block/chunks of the objects from the closest datanodes
- Topology aware placement policy
  - Trade-off between reliability and performance.

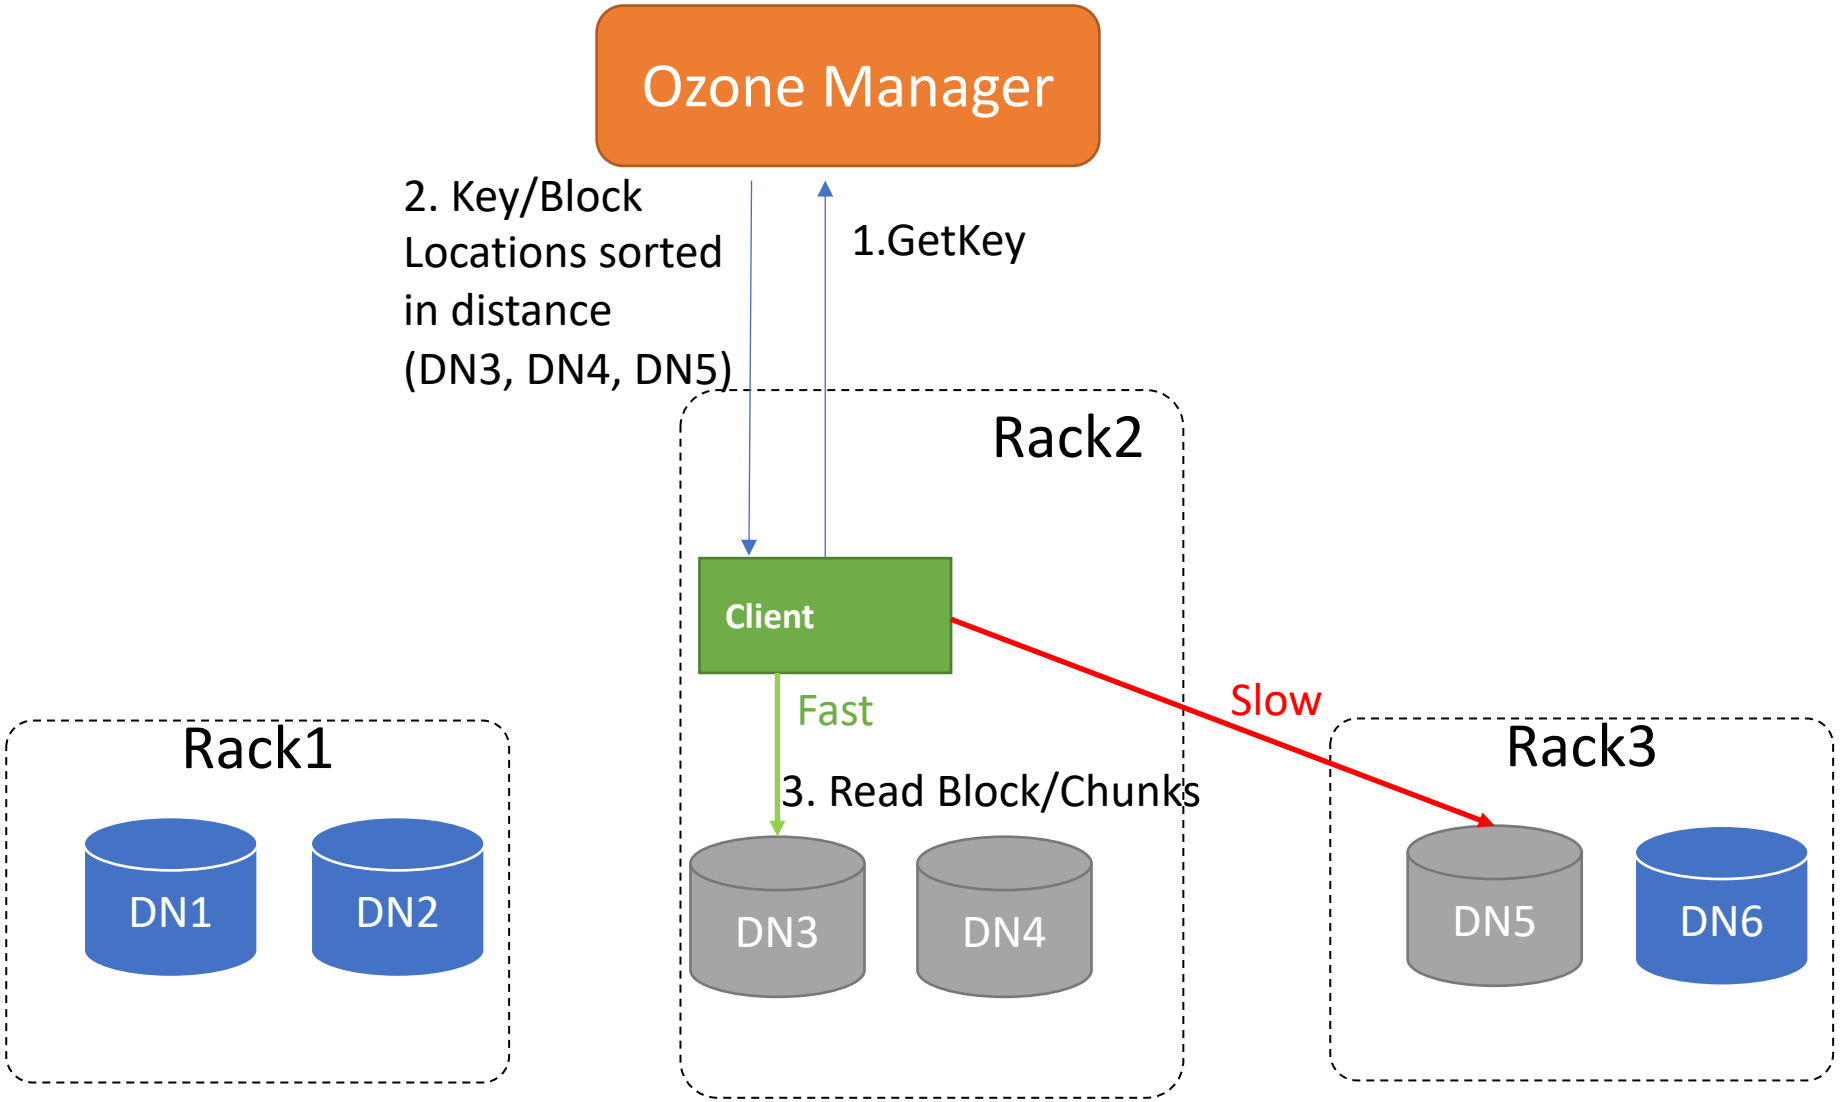
Customize Ozone Topology

```
type: ROOT

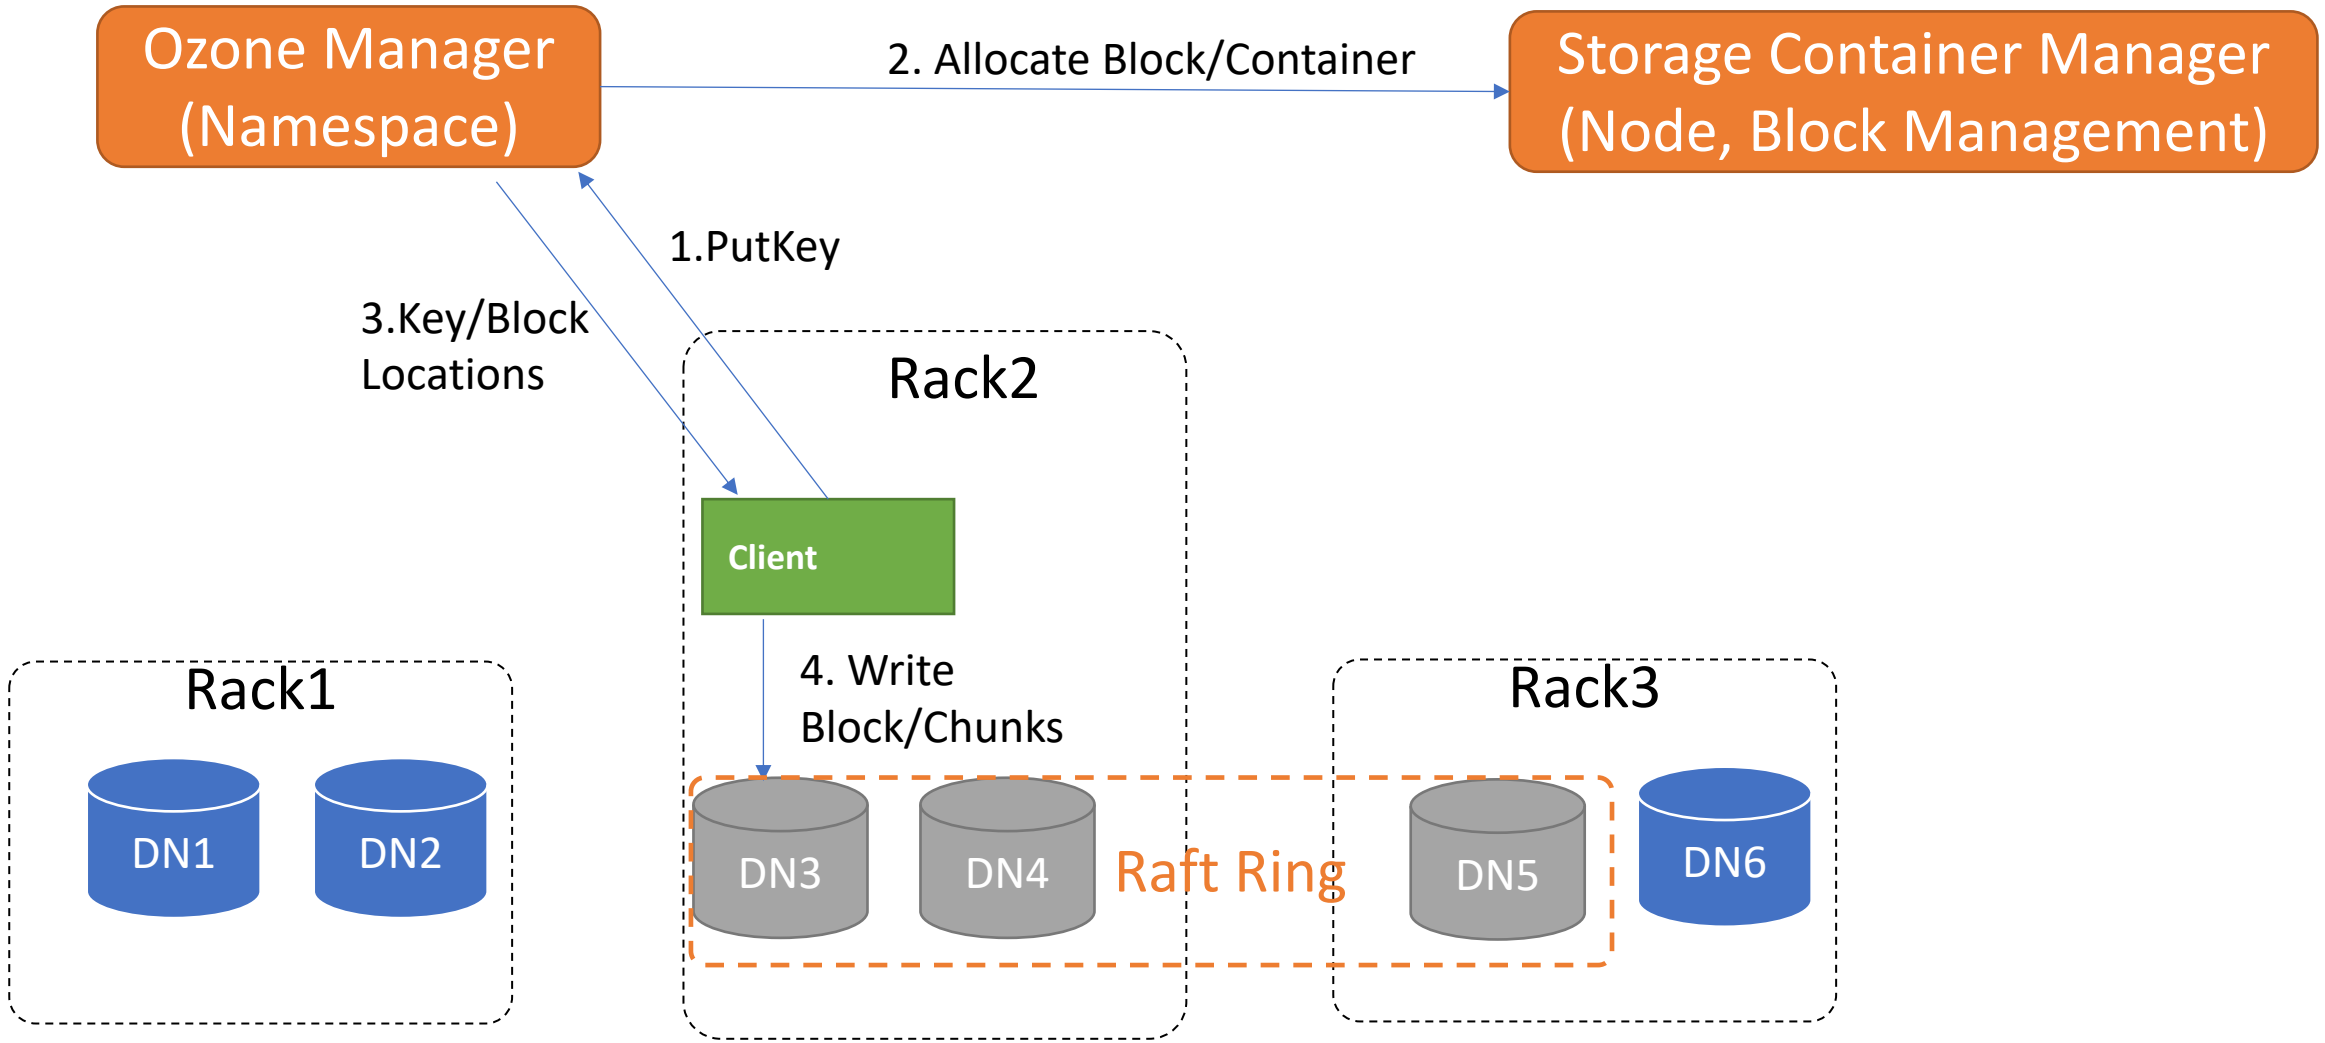
# Layer name
defaultName: root

# Sub layer
# The sub layer property defines as a list which can reflect a node tree, though
# in schema template it always has only one child.
sublayer:
  -
    cost: 1
    prefix: dc
    defaultName: datacenter
    type: INNER_NODE
    sublayer:
      -
        cost: 1
        prefix: rack
        defaultName: rack
        type: INNER_NODE
        sublayer:
          -
            cost: 1
            prefix: ng
            defaultName: nodegroup
            type: INNER_NODE
            sublayer:
              -
                defaultName: node
                type: LEAF_NODE
                prefix: node
```

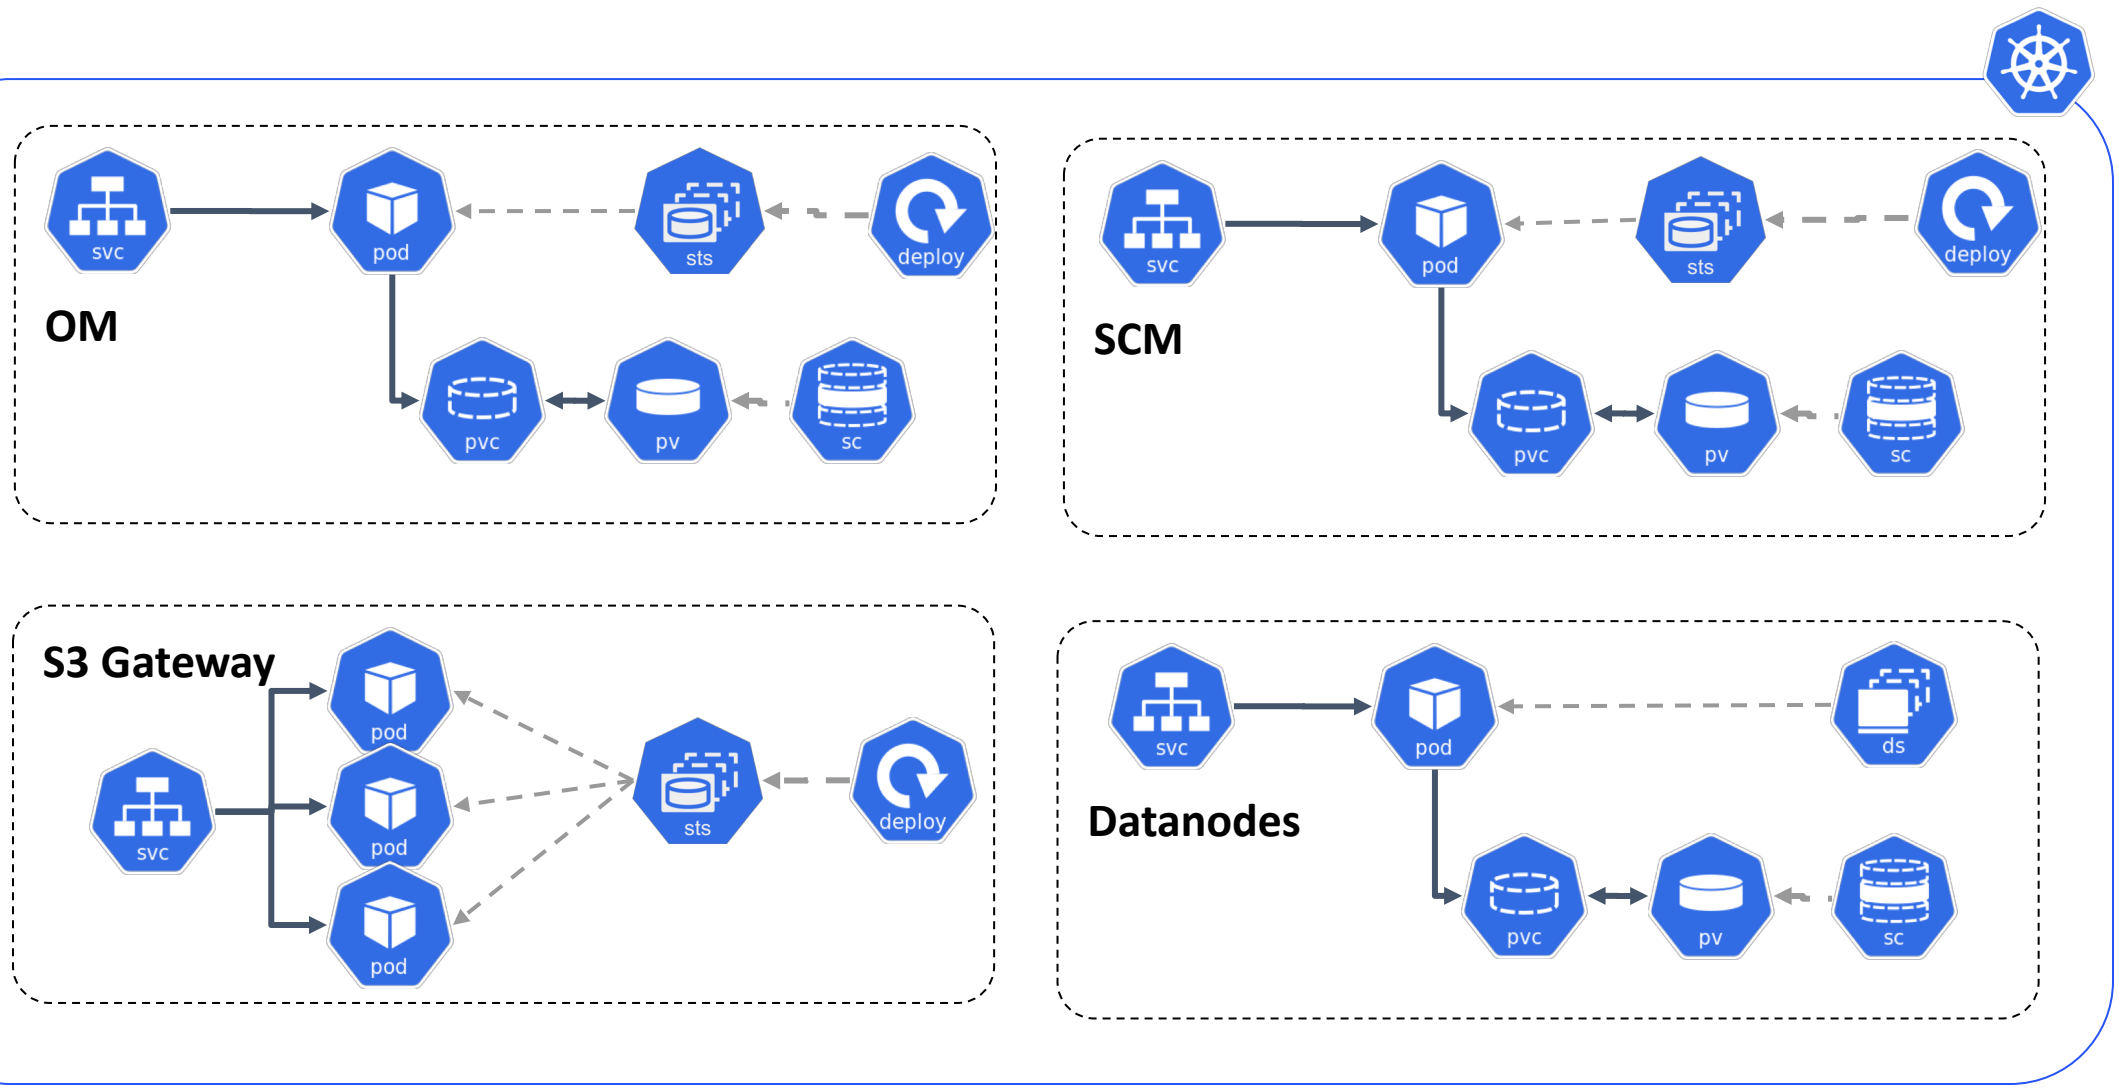
Apache Ozone Topology aware Read



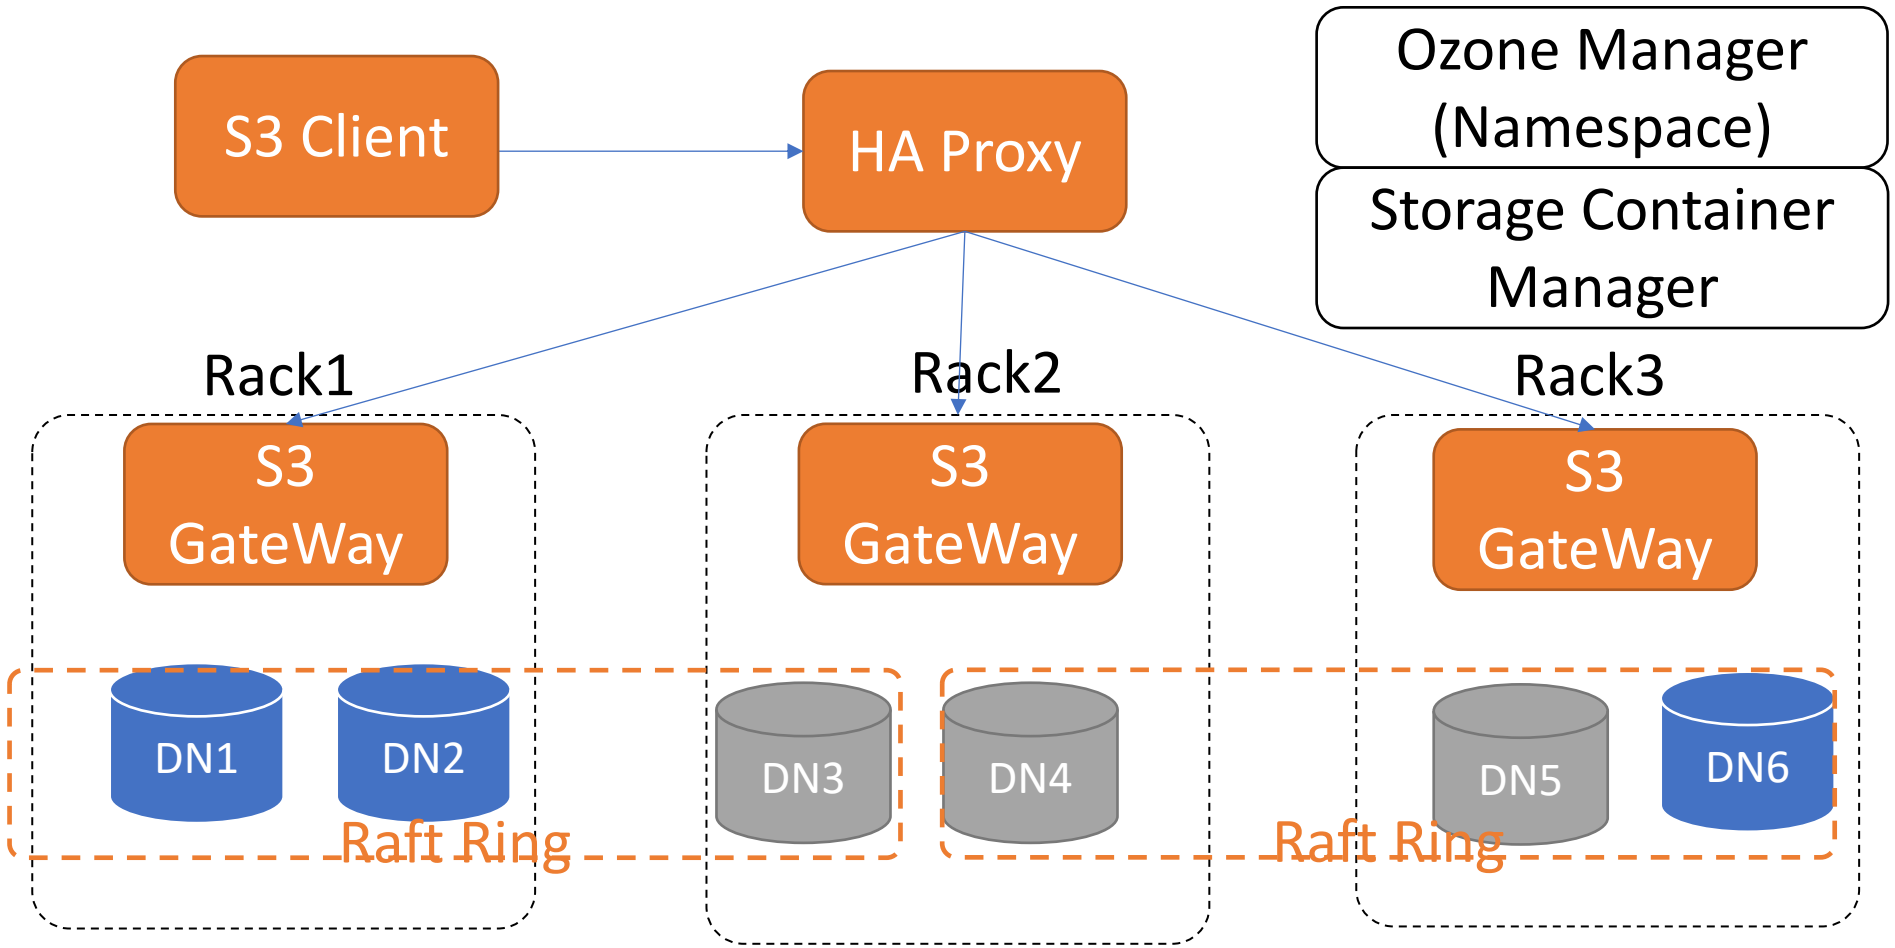
Apache Ozone Topology aware Write



Apache Ozone in Kubernetes



Apache Ozone S3 Gateway



Apache Ozone in Kubernetes RoadMap

- Hadoop Compatible File System (Ozone-0.2.1)
  - Natively support Spark/Yarn/Hive
- Ozone S3 Gateway (Ozone-0.3.0)
  - Access Ozone via S3 API
  - Horizontally scalable with multiple stateless S3 gateways
- Ozone Deployment in Kubernetes (Ozone-0.4.0)
  - Customizable resource definition for ozone services
  - Support Spark + Ozone on Kubernetes

Apache Ozone in Kubernetes RoadMap

- Ozone CSI driver (Ozone-0.4.1)
  - Mount Ozone S3 bucket as CSI volume
  - Consumed as raw Kubernetes Storage
- Ozone Operator
  - Rook integration as storage provider in Rook
  - https://github.com/rook/rook/issues/3235
