Descriptive Analysis

R for Stata Users

Luiza Andrade, Marc-Andrea Fiorina, Rob Marty, Maria Reyes Retana, Rony Rodriguez Ramirez, Luis Eduardo San Martin, Leonardo Viotti
The World Bank | WB Github

March 2024

Introduction

Initial Setup

If You Attended Session 2 | If You Did Not Attend Session 2

1. Go to the `dime-r-training-mar2024` folder that you created yesterday, and open the `dime-r-training-mar2024` R project that you created there.

Introduction

Initial Setup

If You Attended Session 2 | If You Did Not Attend Session 2

1. Open RStudio.
2. Type in the following lines, replacing "YOURFILEPATHHERE" with a file path where the file path where you will place this R project.

```
install.packages("usethis")
library(usethis)
usethis::use_course(
    "https://github.com/worldbank/dime-r-training/archive/main.zip",
    destdir = "YOURFILEPATHHERE"
)
```

3. In the console, type in the requisite number to delete the .zip file (we don't need it anymore)

4. A new RStudio environment will open. Use this for the session today.

Table of contents

Workflows for outputs

Not reproducible

Anything that requires

Copy-pasting

Manual formatting after exported

Reproducible

R Markdown: dynamic document containing code and text that is exported directly from R into PDF, HTML, Word, Power Point and other formats

LaTeX: typesetting system used for scientific publications that automatically reloads tables and figures every time the document is rendered

Setting the stage

Load the packages that we will use today

```
# Install new packages
install.packages("modelsummary")
install.packages("fixest")
install.packages("janitor")
install.packages("huxtable")
install.packages("openxlsx")
```

```
# Load packages
library(here)
library(tidyverse)
library(modelsummary)
library(fixest)
library(janitor)
library(huxtable)
library(openxlsx)
```

Setting the stage

Load the data that we will use today: Stata's `census` dataset

Tip: Use `here`, as we saw in the data wrangling session.

```
# Load data
 census <-
  read_rds(
    here(
      "DataWork",
      "DataSets",
      "Final",
      "census.rds"
    )
  )
```

02:00

Taking a peek at the data

```
glimpse(census)
```

```
## Rows: 50

```

Quick summary statistics

Exploring a dataset

`summary(x, digits)`

Equivalent to Stata's `codebook`. Its arguments are:

- **x:** the object you want to summarize, usually a vector or data frame
- *digits:* the number of decimal digits to be displayed

Exercise 1 ⌨

Use the `summary()` function to describe the `census` data frame.

00:45

Exploring a dataset

```
summary(census)
```

```
##     state               state2               region        pop

```

Exploring a dataset

Code | Start Over | Run Code

```
1
2
3
```

Summarizing continuous variables

- `summary()` can also be used with a single variable.
- When used with continuous variables, it works similarly to `summarize` in Stata.
- When used with categorical variables, it works similarly to `tabulate`.

Summarizing continuous variables

Exercise 2 ⌨

Use the `summary()` function to display summary statistics for a continuous variable in the `census` data frame.

00:45

Summarizing continuous variables

Exercise 2 ⌨

Use the `summary()` function to display summary statistics for a continuous variable in the `census` data frame.

```
summary(census$pop)
```

```
##      Min.   1st Qu.    Median      Mean   3rd Qu.      Max.
##    401851   1169218   3066433   4518149   5434033  23667902
```

Summarizing continuous variables

Code | Start Over | Run Code

```
1
2
3
```

Summarizing categorical variables

`tabyl(x, ...)`

Equivalent to `tabulate` in Stata, creates a frequency table. Its main arguments are vectors to be tabulated.

- **x:** the object you want to summarize, usually a vector or data frame
- ... additional options as show_na, or show_missing_levels.

Exercise 3 ⌨

Use the `tabyl()` function to display frequency tables for:

1. The variable `region` in the `census` data frame
2. The variables `region` and `state` in the `census` data frame, simultaneously

01:00

Summarizing categorical variables

One way tabulation

```
census %>%
  tabyl(region)
```

region	n	percent
NE	9	0.18
N Cntrl	12	0.24
South	16	0.32
West	13	0.26

Summarizing categorical variables

Two way tabulation

```
census %>%
  tabyl(state, region)
```

state	NE	N Cntrl	South	West
Alabama	0	0	1	0
Alaska	0	0	0	1
Arizona	0	0	0	1
Arkansas	0	0	1	0
California	0	0	0	1
Colorado	0	0	0	1
Connecticut	1	0	0	0

Descriptives tables

Descriptives tables

What if you want to...

- ...export the summary statistics to another software?
- ...customize which statistics to display?
- ...format the table?

Well, then you will need a few more packages

- There are many packages that can be used both for displaying and exporting summary statistics
- Today we will show you a combination of two packages: `modelsummary` and `huxtable`
- We chose this combination because together, they can perform all the tasks we are interested in
- In fact, `modelsummary` can perform most of them by itself -- with the exception of exporting formatted tables to Excel

Exploring datasets with *modelsummary*

The package *modelsummary* contains a family of functions called `datasummary` which can be used to create different types of summary statistics tables. These include:

- `datasummary_skim`, to create descriptive statistics tables
- `datasummary_balance`, to create balance tables
- `datasummary_correlation`, to create a correlation table
- `datasummary_crosstab`, to create a twoway tabulation
- `datasummary`, to create customized descriptive statistics tables

Exploring datasets with *modelsummary*

`datasummary_skim(data, output, ....)`

- **data:** the data set to be summarized, the only required argument
- **output:** the type of output desired
- ....: additional options allow for formatting customization, such as including notes and titles

```
datasummary_skim(
  data,
  type = "numeric",
  output = "default",
  histogram = TRUE,
  title = NULL,
  notes = NULL,
  ...
)
```

Exploring datasets with *modelsummary*

Exercise 4 ⌨

Use `datasummary_skim()` to create a descriptive statistics table for the `census` data.

00:45

Exploring datasets with *modelsummary*

```
datasummary_skim(census)
```

	Unique (#)	Missing (%)	Mean	SD	Min	Median	Max	
pop	50	0	4518149.4	4715037.8	401851.0	3066433.0	23667902.0	
poplt5	50	0	326277.8	331585.1	35998.0	227467.5	1708400.0	
pop5_17	50	0	945951.6	959372.8	91796.0	629654.0	4680558.0	
pop18p	50	0	3245920.1	3430531.3	271106.0	2175130.0	17278944.0	
pop65p	50	0	509502.8	538932.4	11547.0	370495.0	2414250.0	
popurban	50	0	3328253.2	4090177.9	172735.0	2156905.0	21607606.0	medage	37	0	29.5	1.7	24.2	29.8	34.7	
death	50	0	39474.3	41742.3	1604.0	26176.5	186428.0	
marriage	50	0	47701.4	45130.4	4437.0	36279.0	210864.0	
divorce	50	0	23679.4	25094.0	2142.0	17112.5	133541.0	
Exploring datasets with *modelsummary*

Code | Start Over | Run Code

```
1
2
3
```

Exploring datasets with *modelsummary*

- *modelsummary* summarizes only numeric variables by default.
- To summarize categorical variables, use the argument `type`

```
datasummary_skim(census, type = "categorical")
```

data	N	%
NE	9	18.0
N Cntrl	12	24.0
South	16	32.0
West	13	26.0

Exploring datasets with *modelsummary*

You can also customize the variables and statistics to include using a **formula** with the `datasummary()` function.

`datasummary(formula, data, output, ...)`

- **formula:** a two-sided formula to describe the table: rows ~ columns
- **data:** the data set to be summarized
- *output:* the type of output desired
- *...*: additional options allow for formatting customization

```
datasummary(
  var1 + var2 + var3 ~ stat1 + stat2 + stat3 + stat4,
  data = data
)
```

Exploring datasets with *modelsummary*

Exercise 5 ⌨

Create a table showing the number of observations, mean, standard deviation, minimum, maximum and median value for all the population, number of deaths, number of marriage and number of divorces in the `census` data.

```
datasummary(
  var1 + var2 + var3 ~ stat1 + stat2 + stat3 + stat4,
  data = data
)
```

> **Tip:** some of the allowed statistics are N, Mean, SD, Min, Max, Median, P0, P25, P50, P75, P100, Histogram

01:30

Exploring datasets with *modelsummary*

```
datasummary(
  pop + death + marriage + divorce ~ N + Mean + SD + Median + Min + Max,
  data = census
)
```

	N	Mean	SD	Median	Min	Max
pop	50	4518149.44	4715037.75	3066433.00	401851.00	23667902.00
death	50	39474.26	41742.35	26176.50	1604.00	186428.00
marriage	50	47701.40	45130.42	36279.00	4437.00	210864.00
divorce	50	23679.44	25094.01	17112.50	2142.00	133541.00

Exploring datasets with *modelsummary*

```
datasummary(
  All(census) ~ N + Mean + SD + Median + Min + Max,
  data = census
)
```

	N	Mean	SD	Median	Min	Max
pop	50	4518149.44	4715037.75	3066433.00	401851.00	23667902.00
poplt5	50	326277.78	331585.14	227467.50	35998.00	1708400.00
pop5_17	50	945951.60	959372.83	629654.00	91796.00	4680558.00
pop18p	50	3245920.06	3430531.31	2175130.00	271106.00	17278944.00
pop65p	50	509502.80	538932.38	370495.00	11547.00	2414250.00
popurban	50	3328253.18	4090177.93	2156905.00	172735.00	21607606.00
medage	50	29.54	1.69	29.75	24.20	34.70

marriage	50	47701.40	45130.42	36279.00	4437.00	210864.00
divorce	50	23679.44	25094.01	17112.50	2142.00	133541.00

Balance tables with *modelsummary*

```
census_rct <-
  census %>%
  mutate(
    treatment = as.numeric(runif(n()) > 0.5)
  ) %>%
  select(
    -starts_with("state")
  )

datasummary_balance(
  ~ treatment,
  data = census_rct
)
```

Balance tables with *modelsummary*

		0		1			
		Mean	**Std. Dev.**	**Mean**	**Std. Dev.**	**Diff. in Means**	**Std. Error**

	West	6	40.0	7	20.0		

Exporting tables

Exporting *modelsummary* table to LaTeX

To export the tables we created, we can simply use the option `output`:

```
descriptives <-
  All(census) ~ N + Mean + SD + Median + Min + Max

datasummary(
  descriptives,
  data = census,
  output = here( # file path to output file
    "DataWork",
    "Output",
    "Raw",
    "summary-stats.tex"
  )
)
```

Exporting *modelsummary* table

Other valid output formats include:

- `.docx`
- `.pptx`
- `.html`
- `.md`

Exporting *modelsummary* table

Other valid output formats include:

- `.docx`
- `.pptx`
- `.html`
- `.md`
- … but not `.xls`

Exporting *modelsummary* table to Excel

- To export the table to Excel, we will first convert it into an object of type *huxtable*
- `huxtable` is another R package, one that allows not only for exporting tables, but also for extensive customization
- Before getting to the customization part, however, let's export this table:

```
# Create the huxtable object
summary_stats_table <-
  datasummary(
    descriptives,
    data = census,
    output = "huxtable"
  )

# Export it to Excel
quick_xlsx(
  summary_stats_table, # object to be exported
  file = here( # file path to output file
    "DataWork",
    "Output",
    "Raw",
    "summary-stats.xlsx"
  )
)
```

Exporting tables

A similar code can also export the same table to a self-standing LaTeX document

```
# Export to LaTeX
quick_latex(
  summary_stats_table,
  file = here(
    "DataWork",
    "Output",
    "Raw",
    "summary-stats.tex"
  )
)
```

Exporting tables to different Excel tabs

```
# Start a new workbook
wb <- createWorkbook()

# Add one sheet to it
wb <-
  as_Workbook(
    summary_stats_table,
    Workbook = wb,
    sheet = "Summary stats"
  )

# Add another sheet to it
wb <-
  as_Workbook(
    hux("Mock", "table"),
    Workbook = wb,
    sheet = "Other sheet"
  )

# Save the workbook
saveWorkbook(
  wb, # object to be saved
   file = here( # file path to output file
    "DataWork",
    "Output",
    "Raw",
    "summary-stats.xlsx"
  ),
  overwrite = TRUE # replace existing file
)
```

Exporting tables to LaTeX fragment

```
summary_stats_table %>%
  print_latex() %>% # See LaTeX code
  # Save LaTeX code
  capture.output(
    file = here(
      "DataWork",
      "Output",
      "Raw",
      "summary-stats.tex"
    )
  )
```

You will also need to load the required LaTeX packages. To copy the code that creates a preamble with all of them, use this code:

```
report_latex_dependencies()
```

Formatting tables

Beautifying tables

- `huxtable` also allows you to customize table formatting so it can be exported with the same layout to multiple software
- Before we do that, however, we will create a version of the data where the variable names are the Stata labels

```
# Extract variable labels from data frame
labels <- names(census)
names(labels) <- attributes(census)$var.labels

# Rename the variables
census_labelled <-
  census %>%
  rename(
    labels
  )

# Create a labelled summary table
summary_stats_table <-
  datasummary(
    All(census_labelled) ~ N + Mean + SD + Median + Min + Max,
    data = census_labelled,
    output = "huxtable"
  )
```

Beautifying tables

The code below shows the table `summary_stats_table` can be formatted

```
# Format table
summary_stats_table %>%
 # Use first row as table header
 set_header_rows(1, TRUE) %>%
 # Use first column as row header
 set_header_cols(1, TRUE)  %>%
 # Don't round large numbers
 set_number_format(everywhere, 2:ncol(.), "%9.0f") %>%
 # Centralize cells in first row
 set_align(1, everywhere, "center") %>%
 # Set a theme for quick formatting
 theme_basic()
```

	N	Mean	SD	Median	Min	Max

Ok, can we run some regressions now?!

Running regressions

The base R command for linear regressions is called `lm`

lm(formula, data, subset, weights, ...)

- **formula:** an object of class "formula" containing a symbolic description of the model
- **data:** a data frame containing the variables indicated in the formula
- *subset:* an optional vector specifying a subset of observations to be used in the regression
- *weights:* an optional vector of weights to be used in the regression

Formulas can take three specifications:

- `y ~ x1 + x2` regresses variable `y` on covariates `x1` and `x2`
- `y ~ x1:x2` regresses variable `y` on the interaction of covariates `x1` and `x2`
- `y ~ x1*x2` is equivalent to `y ~ x1 + x2 + x1:x2`

Running regressions

Exercise 6 ⌨

Using the `census` data, run a regression of the number of divorces on population, urban population and number of marriages.

```
lm(y ~ x1 + x2,
   data)
```

01:00

Running regressions

Exercise 6 ⌨

Using the `census` data, run a regression of the number of divorces on population, urban population and number of marriages.

```
reg1 <-
  lm(
    divorce ~ pop + popurban + marriage,
    census
  )
```

Running regressions

- The output of regression commands is a list of relevant information.
- By default, it prints only a small portion of this information.
- The best way to visualize results is to store this list in an object and then access its contents using the function `summary`

Running regressions

```
reg1 <-
  lm(
    divorce ~ pop + popurban + marriage,
    census
  )

summary(reg1)
```

```
##
## Call:
## lm(formula = divorce ~ pop + popurban + marriage, data = census)
##
## Residuals:
##      Min       1Q   Median       3Q      Max
## -22892.3  -1665.1    796.5   4138.0  17212.2
##
## Coefficients:
##              Estimate Std. Error t value Pr(>|t|)
## (Intercept) 1.207e+02  1.838e+03   0.066    0.948
## pop         1.044e-03  1.633e-03   0.639    0.526
## popurban    1.954e-03  1.796e-03   1.088    0.282
## marriage    2.587e-01  5.958e-02   4.342  7.7e-05 ***
## ---
## Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
##
## Residual standard error: 7466 on 46 degrees of freedom
## Multiple R-squared:  0.9169,    Adjusted R-squared:  0.9115
## F-statistic: 169.2 on 3 and 46 DF,  p-value: < 2.2e-16
```

Running regressions

The `feols` command from package `fixest` allows for more flexibility in model specification

feols(formula, data, subset, weights, ...)

- **formula:** an object of class "formula" containing a symbolic description of the model
- **data:** a data frame containing the variables indicated in the formula
- *vcov:* one of "iid", "hetero" (or "HC1"), "cluster", "twoway", "NW" (or "newey_west"), "DK" (or "driscoll_kraay"), or "conley"
- *subset:* an optional vector specifying a subset of observations to be used in the regression
- *weights:* an optional vector of weights to be used in the regression
- *cluster:* a list of vectors, a character vector of variable names, a formula or an integer vector specifying how to cluster standard errors
- ...

Running regressions

Formulas for `feols` are more complex, and take the following format: `y ~ x1 + x2 | fe1 + fe2 | x3 ~ iv3`

- `y ~ x1 + x2` takes all the same formulas as `lm`
- `fe1 + fe2` list the variables to be included as fixed effects
- `x3 ~ iv3` uses instrument `iv3` for variable `x3`

Running regressions

Exercise 7 ⌨

Using the `census` data, run a regression of the number of divorces on population, urban population and number of marriages controlling for region fixed effects.

```
feols(
  y ~ x1 + x2 | fe1 + fe2,
  data
)
```

01:00

Running regressions

Exercise 7 ⌨

Using the `census` data, run a regression of divorce on population, urban population and number of marriages controlling for region fixed effects.

```
reg2 <-
  feols(
    divorce ~ pop + popurban + marriage | region,
    census,
    se = "iid"
  )

summary(reg2)
```

Running regressions

```
reg2 <-
  feols(
    divorce ~ pop + popurban + marriage | region,
    census,
    se = "iid"
  )

summary(reg2)
```

```
## OLS estimation, Dep. Var.: divorce
## Observations: 50
## Fixed-effects: region: 4
## Standard-errors: IID
##          Estimate Std. Error  t value  Pr(>|t|)
## pop      0.000395   0.001788 0.220981 0.8261531
## popurban 0.003553   0.001998 1.778249 0.0824344 .
## marriage 0.183659   0.058027 3.165064 0.0028471 **
## ---
## Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
## RMSE: 6,257.6     Adj. R2: 0.927695
##                 Within R2: 0.935434
```

Some notes on regressions

- Whenever a factor is included in the list of covariates, it is treated as a categorical variable, i.e., as if you had written `i.x` in Stata.
- Whenever a boolean is included in the list of covariates, it is treated as a dummy variable, where `TRUE` is `1` and `FALSE` is `0`.

Exporting regression tables

Exporting regression tables

`huxtable` also has a quick wrapper for regression tables

huxreg(...)

- **...**: Models, or a single list of models. Names will be used as column headings.
- *number_format:* Format for numbering. See number_format() for details.
- *stars:* Levels for p value stars.
- *bold_signif:* Where p values are below this number, cells will be displayed in bold.
- *note:* Footnote for bottom cell, which spans all columns.
- *statistics:* A vector of summary statistics to display.
- *coefs:* A vector of coefficients to display. To change display names, name the coef vector: c("Displayed title" = "coefficient_name", ...)

Exporting regression tables

```
huxreg(reg1, reg2)
```

	(1)	(2)
(Intercept)	120.730	
	(1838.216)	
pop	0.001	0.000
	(0.002)	(0.002)
popurban	0.002	0.004
	(0.002)	(0.002)
marriage	0.259 ***	0.184 **
	(0.060)	(0.058)
N	50	50
R2	0.917	0.937
logLik	-514.766	-508.024
AIC	1039.531	1030.048
*** p < 0.001; ** p < 0.01; * p < 0.05.		

Formatting regression tables

```
huxreg(
  reg1, reg2,
  # Show variable labels instead of names
   coefs = c(
     "Population" = "pop",
     "Urban population"  = "popurban",
     "Number of marriages" = "marriage"
   ),
   statistics = c("N. obs." = "nobs")) %>%
   add_rows(
     c("Region FE", "No", "Yes"),
     after = 7
   )
```

	(1)	(2)
Population	0.001	0.000
	(0.002)	(0.002)
Urban population	0.002	0.004
	(0.002)	(0.002)
Number of marriages	0.259 ***	0.184 **
	(0.060)	(0.058)
Region FE	No	Yes
N. obs.	50	50
*** p < 0.001; ** p < 0.01; * p < 0.05.		

Exporting regression tables

Exercise 8 ⌨

Export a regression table with the results of your estimations using `lm` and `feols`:

- Use `huxreg` to combine `reg1` and `reg2`.
- Use `quick_xlsx` or `quick_latex` to export the output of `huxreg` to your preferred format.

```
# Combine regression results with huxreg
reg_table <- huxreg(reg1, reg2)

# Export to Excel
quick_xlsx(reg_table,  file = here(
                              "DataWork",
                              "Output",
                              "Raw",
                              "regression_table.xlsx"
```

```
# Or, export to LaTeX
quick_latex(reg_table, file = here(
                                   "DataWork",
                                   "Output",
                                   "Raw",
                                   "regression_table.tex")
```

01:00

Appendix

Aggregating observations

Aggregating observations

- If you want to show aggregated statistics, the function `summarise` is a powerful tool.
- It is similar to `datasummary` in that it calculates a series of statistics for a data frame.
- However, it does not have pre-defined statistics, so it requires more manual input.
- On the other hand, its output is a regular data frame, so it is also useful to create constructed data sets.
- Its Stata equivalent would be `collapse`

Aggregating observations

`summarise(.data, ...)`

- **data**: the data frame to be summarized
- **...**: Name-value pairs of summary functions. The name will be the name of the variable in the result.

The "name-value" pairs mentioned under `...` look like this: `new_variable = function(existing_variable)`, where possible functions include:

- Center: `mean()`, `median()`
- Spread: `sd()`, `IQR()`, `mad()`
- Range: `min()`, `max()`, `quantile()`
- Count: `n()`, `n_distinct()`

Aggregating observations

```
region_stats <-
  census %>%
  group_by(region) %>%
  summarise(
    `Number of States` = n_distinct(state),
    `Total Population` = sum(pop)
  )
```

region	Number of States	Total Population
NE	9	49135283
N Cntrl	12	58865670
South	16	74734029
West	13	43172490

Aggregating observations

Exercise 9 ⌨

Recreate the `region_stats` data set, now including the average and the standard deviation of the population.

01:30

Aggregating observations

```
region_stats <-
  census %>%
  group_by(region) %>%
  summarise(
    `Number of States` = n_distinct(state),
    `Total Population` = sum(pop),
    `Average Population` = mean(pop),
    `SD of Population` = sd(pop)
  )
```

region	Number of States	Total Population	Average Population	SD of Population
NE	9	49135283	5459476	5925235
N Cntrl	12	58865670	4905473	3750094
South	16	74734029	4670877	3277853
West	13	43172490	3320961	6217177

Aggregating observations

Exercise 9 ⌨

Use `huxtable` to format and export the object `region_stats`.

02:00

Aggregating observations

```
region_stats_table <-
  region_stats %>%
  rename(Region = region) %>%
  as_hux %>%
  set_header_cols("Region", TRUE)  %>%
  theme_bright()

quick_xlsx(
  region_stats_table,
   file = here(
     "DataWork",
     "Output",
     "Raw",
     "region-stats.xlsx"
   )
)
```
